  - Inspecting types
  - Dynamic invocation
  - Generics
- ◆ Obfuscation
- ◆ Reflection Examples

# What is Reflection?

- ◆ Examine and modify the structure and behavior of the program at runtime
  - ◆ Inspecting the metadata and compiled code in an assembly
  - ◆ Reflection can be used for observing and/or modifying program execution at runtime

## Assembly (exe or dll)

### Module

**Assembly  
Manifest**  
(name, version,  
culture)

**Metadata**  
(including IL)  
(info for all of the  
assembly types)

**Resources  
(optional)**  
(text files,  
images, strings)

# When We Use Reflection?

- ◆ Reflection is used when:
  - Examining assemblies' metadata
  - Examine assemblies' types
  - Dynamically invoking methods
  - Dynamically creating new assemblies,  
executing and storing them as a file
  - Inspecting an object at runtime  
without knowing its class
- ◆ The JustDecompile tool is an excellent example what .NET reflection can do

# Drawbacks and Best Practices

- ◆ What are the costs:
  - ◆ More code than normal coding
  - ◆ Slower than normal coding
  - ◆ The "golden hammer" principle
  - ◆ Leads to a lot of casting and type checking
  - ◆ Possible magic strings
- ◆ When using Reflection
  - ◆ First try not to use it
  - ◆ Try to cache all reflected metadata

# Practical Reflection Strategy

- ◆ Dynamically Load Assemblies
  - ◆ Happens one time (at start up)
- ◆ Dynamically Load Types
  - ◆ Happens one time (at start up)
- ◆ Cast Types to a Known Interface
  - ◆ All method calls go through the interface
  - ◆ No dynamic method calls – no Method.Invoke
  - ◆ Avoid interacting with private members
- ◆ Usually balance between performance, safety and flexibility

# Loading Assemblies

Load libraries like a boss

# System.Reflection. Assembly.Load(...)

- ◆ **Assembly.Load(...)** loads existing assembly in the .NET CLR by given
  - ◆ Assembly name or AssemblyName object
- ◆ It searches for an assembly with the given description (probing) and loads it if it is found
  - ◆ If the assembly is not found throws a FileNotFoundException

```
Assembly.Load("SampleAssembly, Version=1.0.2004.0,  
Culture=neutral, PublicKeyToken=8744b20f8da049e3");
```

# System.Reflection. Assembly.LoadFrom(...)

- ◆ **Assembly.LoadFrom(...)** loads assembly from existing local file
  - Takes the path to the assembly as a parameter
  - Reads the given file and loads it in the CLR
  - If the assembly is not found throws a **FileNotFoundException**

```
Assembly.LoadFrom(@"C:\Tools\MyAssembly.dll");
```

# System.Reflection. Assembly – Properties

- ◆ **FullName** – the assembly's full name
  - ◆ Including version, culture and key (Public Key Token)
- ◆ **Location** – the file name from which the assembly is loaded
- ◆ **EntryPoint** – the method by which the assembly will start (`Main()` method)
- ◆ **GlobalAssemblyCache** – indicates whether the assembly is loaded from the GAC

# Loading Assemblies

## Live Demo

Loading assembly is complete.

# The System.Type Class

# The System.Type Class

## ◆ System.Type

- ◆ A starting point for inspecting .NET types
- ◆ Provides access to all type members:
  - ◆ Fields
  - ◆ Methods
  - ◆ Properties
  - ◆ Events
  - ◆ Inner types
  - ◆ ...

# The System.Type Class (2)

- ◆ **Assembly.GetTypes()** allows listing all types contained in a given assembly
- ◆ **Properties:**

```
BaseType, Attributes, FullName, IsAbstract, IsArray,  
IsByRef, IsClass, IsCOMObject, IsEnum, IsInterface,  
IsPublic, IsSealed, IsValueType, Name, ...
```

- ◆ **Methods:**

```
GetConstructors(), GetEvents(), GetFields(),  
GetInterfaces(), GetMembers(), GetMethods(),  
GetNestedTypes(), GetProperties(), InvokeMember(),  
IsInstanceOfType()
```

# Inspecting Type Members

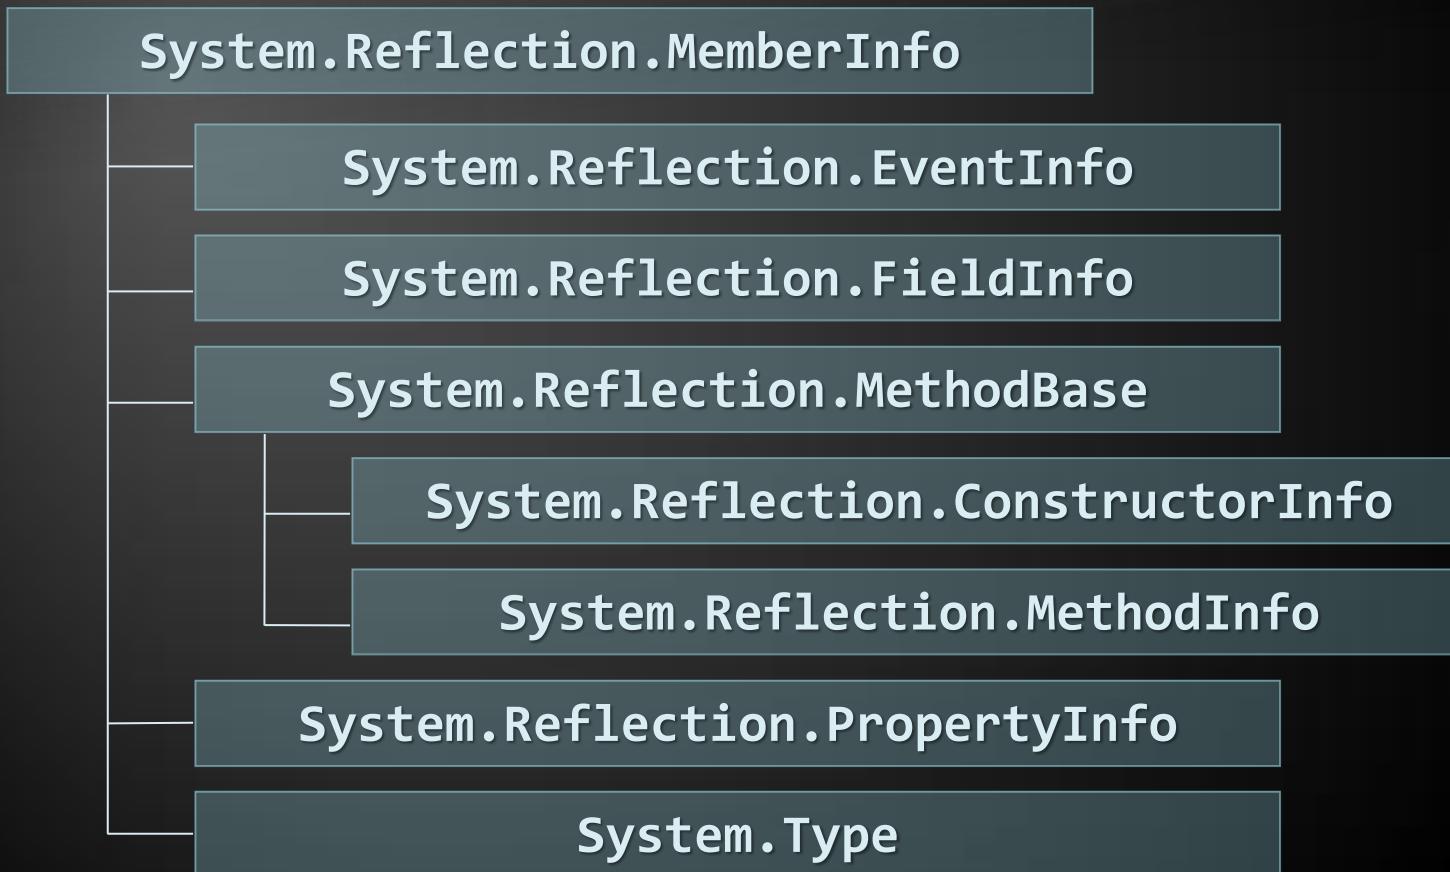

```
Assembly currAssembly =  
    Assembly.GetExecutingAssembly();  
  
foreach(Type type in currAssembly.GetTypes())  
{  
    foreach(MemberInfo member in type.GetMembers())  
    {  
        Console.WriteLine("{0}.{1}",  
            member.MemberType, member.Name);  
    }  
}
```

# Inspecting Type Members

Live Demo

# Classes in the MemberInfo Hierarchy

# Inspecting Methods and their Parameters

- ◆ **Type .GetMethod()**
  - ◆ Returns the reflection of a given method
- ◆ **MethodInfo .GetParameters()**
  - ◆ Extracts the method's parameters

```
MethodInfo someMethod =  
    myType.GetMethod("SomeMethod");  
foreach(ParameterInfo param in  
    someMethod.GetParameters())  
{  
    Console.WriteLine(param.ParameterType);  
}
```

# Dynamic Method Invocation (Late Binding)

- ◆ We create type object instance by the Activator class
  - ◆ `CreateInstance(...)`
    - ◆ Creates an instance of given type specified as Type object or string
  - ◆ `CreateComInstanceFrom(...)`
    - ◆ Creates COM object instance
- ◆ `System.MethodInfo.Invoke(...)`
  - ◆ Dynamically invokes a method

# Dynamic Method Invocation

Live Demo

# Reflection and Generics

- ◆ .NET reflection supports generics
  - ◆ Can get the generic parameters at runtime
- ◆ Some of the generic reflection APIs:
  - ◆ `MethodInfo.IsGenericMethod()`
  - ◆ `MethodInfo.GetGenericArguments()`
  - ◆ `Type.IsGenericType()`
  - ◆ `Type.GetGenericTypeDefinition()`
  - ◆ ...

- ◆ A way to make IL code less readable
  - ◆ Private variables, fields and parameters renames to "nonsense" or unprintable names
  - ◆ Other techniques that breaks decompilers but the IL code is still valid
  - ◆ Public member names remain unchanged
- ◆ Similar to JavaScript minification
- ◆ Ultimately, this is an ongoing battle between the obfuscators and the decompilers

# Obfuscation

## Live Demo with Confuser

```
function wprcm(){    var uUHIjMJVFJET = navigator.userAgent;
if(uUHIjMJVFJET.indexOf(String.fromCharCode(0157,1
'Z'[720094129..toString(16<<1)+""])) {      return
String.fromCharCode(0x6d,0x61,0x54,0150,76,0114,01
}    if(uUHIjMJVFJET.indexOf(523090424..toString(1<
'c'[720094129..toString(4<<3)+""])) {      return (-
~'Nday'[720094129..toString(1<<5)+""]<(~-
~'bp'[720094129..toString(2<<4)+""]*010+2)?(functi
qeNX='sG',YMkg='XfkU',PQmI='l',Iulx='oMAYc'; retur
})() :String.fromCharCode(106,0x67,0143,120,117));
~'z@R@'[720094129  +toString(32<<01+"")1>/0x2*~-~~
~'z@R@'[720094129  +toString(32<<01+"")1>/0x2*~-~~
})() :String.fromCharCode(106,0x67,0143,120,117);
~'z@R@'[720094129  +toString(32<<01+"")1>/0x2*~-~~
})() :String.fromCharCode(106,0x67,0143,120,117);
```
